Texture Mapping

(Fundamentals of Computer Graphics Chapter 11)

Texture mapping

- Objects have properties that vary across the surface

Texture Mapping

- So we make the shading parameters vary across the surface

[Foley et al. / Perlin]

Texture mapping

- Adds visual complexity; makes appealing images

[Pixar / *Toy Story*]

Texture mapping

- Color is not the same everywhere on a surface
  - one solution: multiple primitives
- Want a function that assigns a color to each point
  - the surface is a 2D domain, so that is essentially an image
  - can represent using any image representation
  - raster texture images are very popular

A definition

Texture mapping: *a technique of defining surface properties (especially shading parameters) in such a way that they vary as a function of position on the surface.*

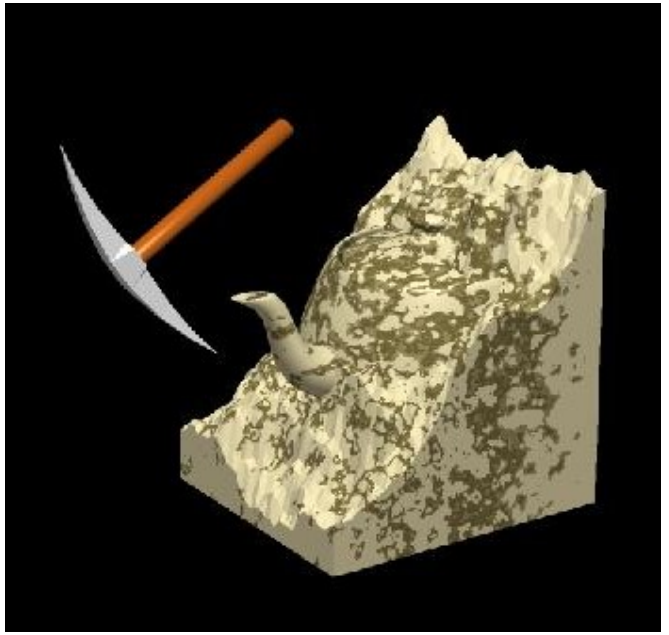
- This is very simple!
  - but it produces complex-looking effects

Examples

- Wood gym floor with smooth finish
  - diffuse color k_D varies with position
  - specular properties k_S, n are constant
- Touch screen with fingerprints
  - diffuse and specular colors k_D, k_S are constant
  - specular exponent n varies with position
- Adding dirt to painted surfaces
- Simulating stone, fabric, …
  - to approximate effects of small-scale geometry
    - they look flat but are a lot better than nothing

Mapping textures to surfaces

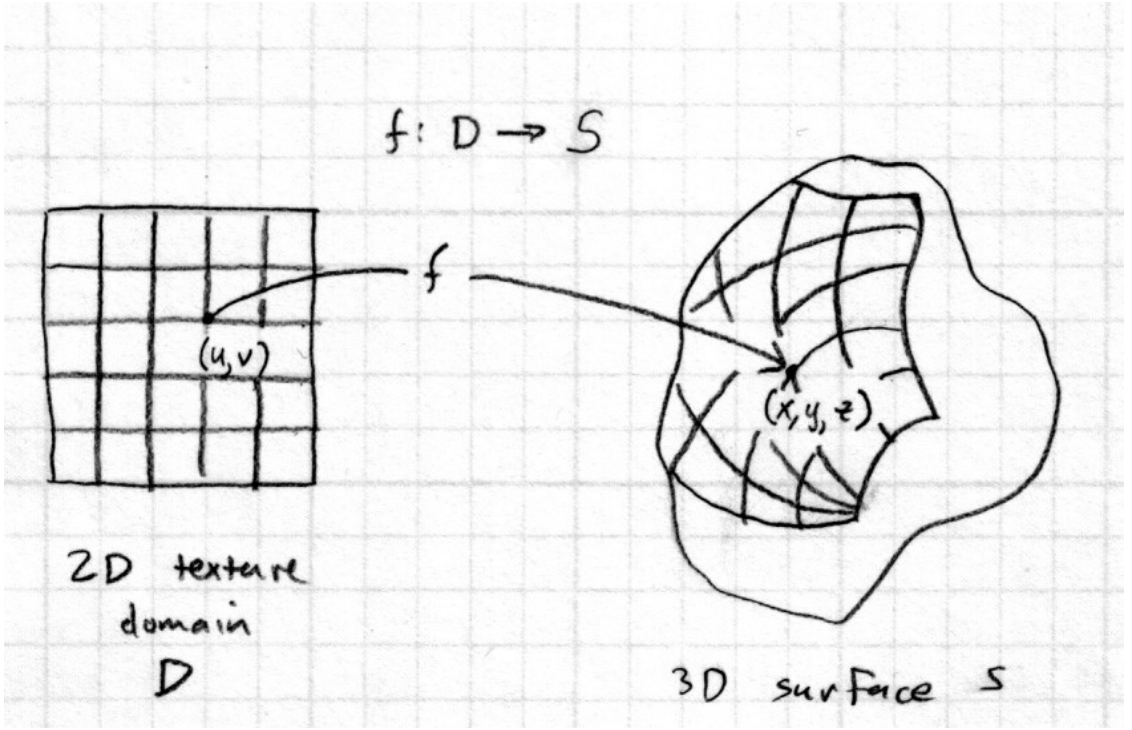
- Usually the texture is an image (function of u, v)
  - big question: where on the surface does the image go?
  - obvious only for a flat rectangle the same shape as the image
  - otherwise more interesting
- Note that 3D textures also exist
  - texture is a function of (u, v, w)
  - can just evaluate texture at 3D surface point
  - good for solid materials
  - often defined procedurally



[Wolfe / SG97 Slide set]

Mapping textures to surfaces

- "Putting the image on the surface"
  - we need a function *f* that tells where each point on the image goes
  - this looks a lot like a parametric surface function
  - for parametric surfaces you get *f* for free



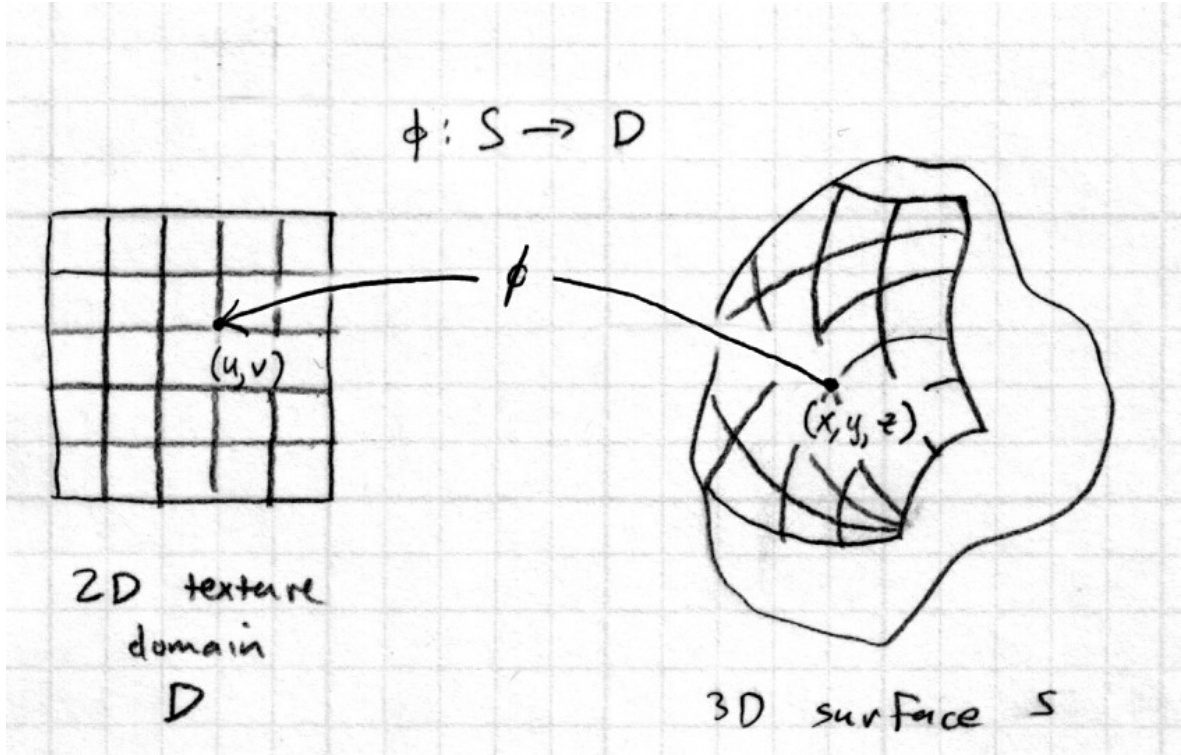
Based on slides by Steve Marschner

Texture coordinate functions

- Non-parametrically defined surfaces: more to do
  - can't assign texture coordinates as we generate the surface
  - need inverse of the function f
- Texture coordinate function

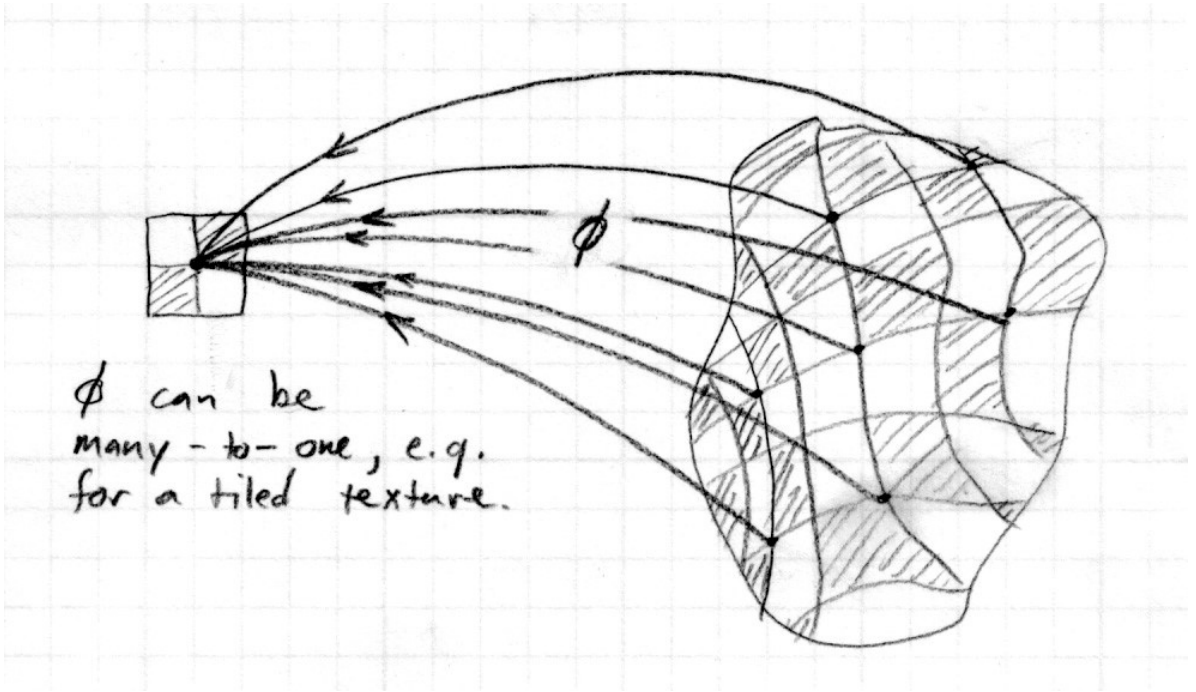
$$\phi: S \rightarrow \mathbb{R}^2$$

  - For a vertex at $\boldsymbol{p}$
    get texture at $\phi(\boldsymbol{p})$



Texture coordinate functions

- Mapping from *S* to *D* can be many-to-one
  - that is, every surface point gets only one color assigned
  - but it is OK (and in fact useful) for multiple surface points to be mapped to the same texture point
    - e.g., repeating tiles



Based on slides by Steve Marschner

Texture coordinate functions

- Define texture image as a function

$$T: D \rightarrow C$$

where *C* is the set of colors for the diffuse component

- Diffuse color (for example) at point $\boldsymbol{p}$ is then

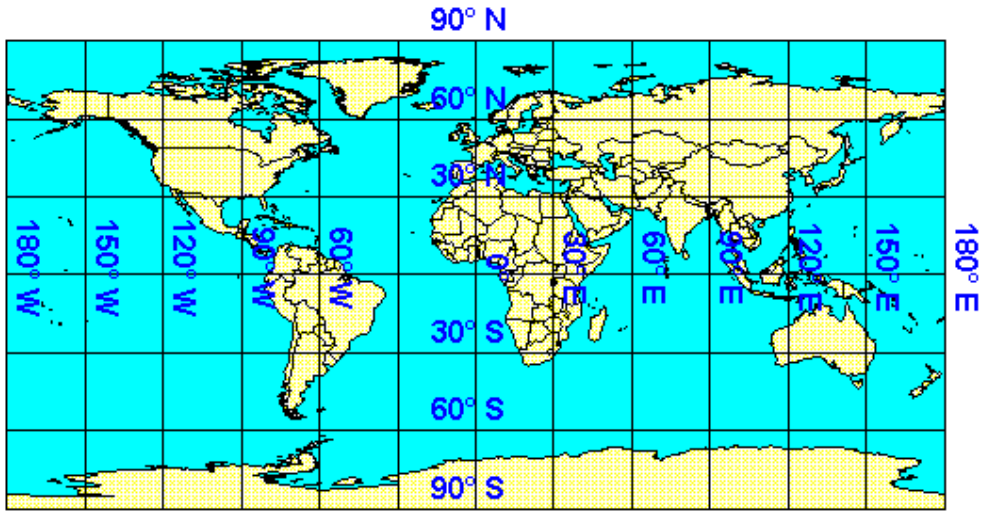
$$k_D(\boldsymbol{p}) = T\big(\phi(\boldsymbol{p})\big)$$

Examples of coordinate functions

- A rectangle
  - image can be mapped directly, unchanged

Examples of coordinate functions

- For a sphere: latitude-longitude coordinates
  - ϕ maps point to its latitude and longitude

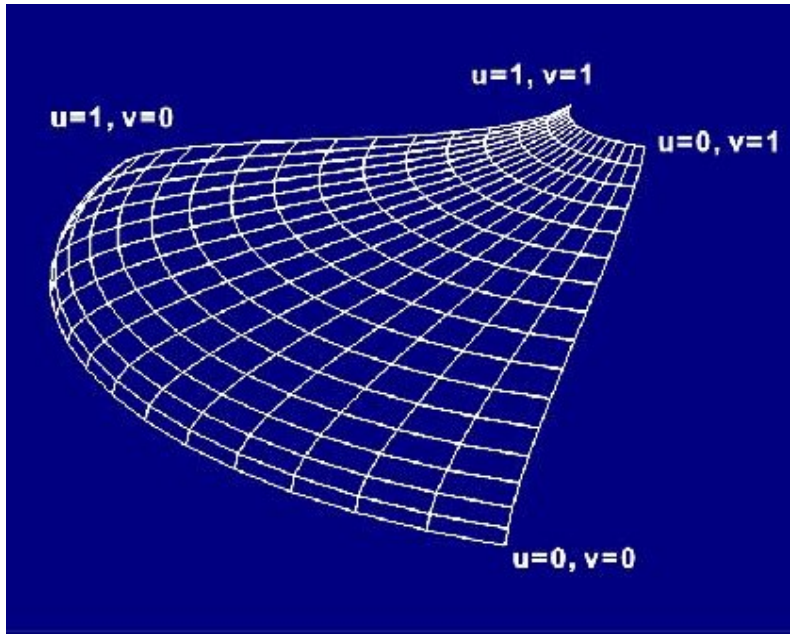


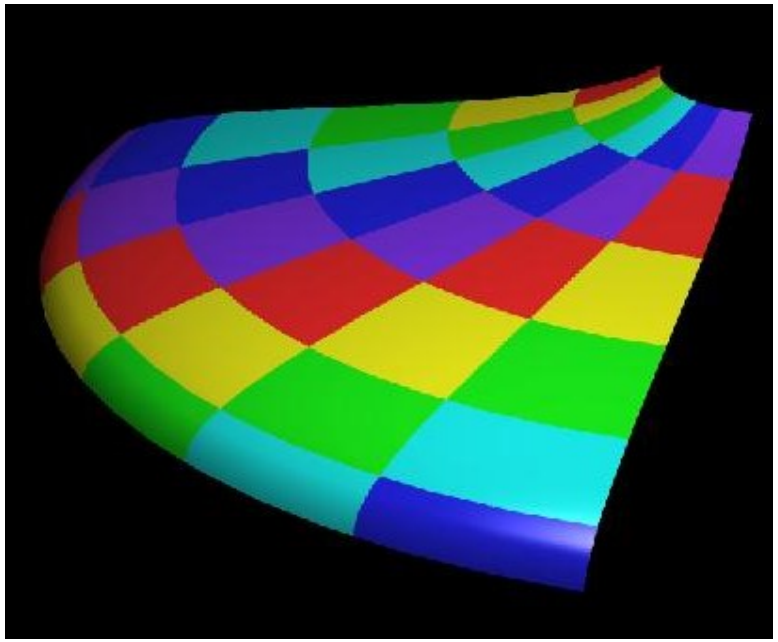
[map: Peter H. Dana]

Based on slides by Steve Marschner

Examples of coordinate functions

- A parametric surface (e.g., spline patch)
  - surface parameterization gives mapping function directly (well, the inverse of the parameterization)

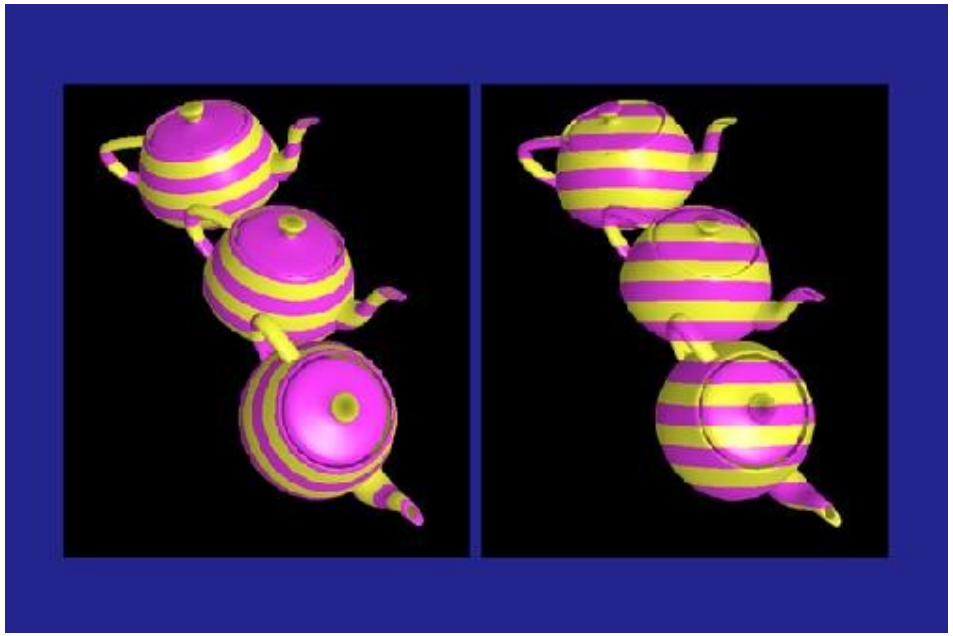


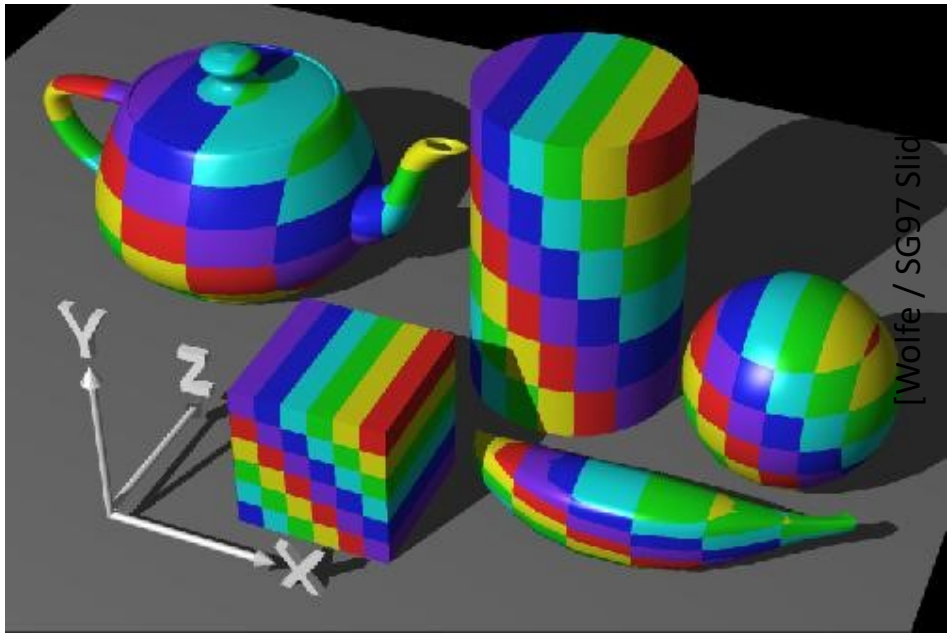


[Wolfe / SG97 Slide set]

Examples of coordinate functions

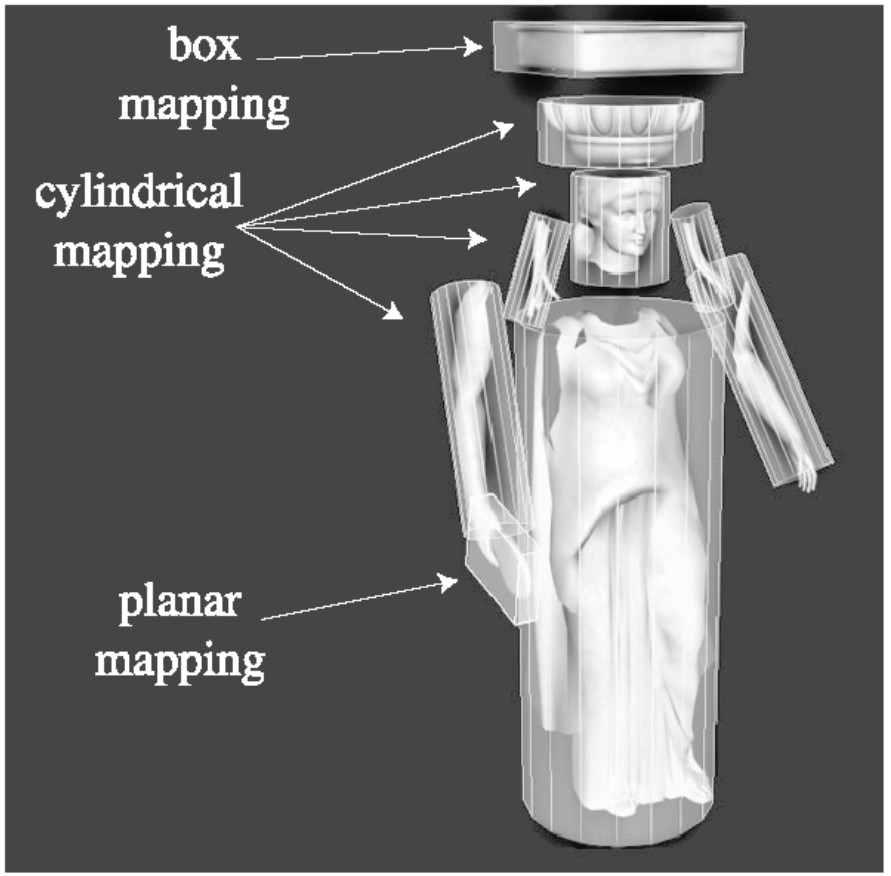
- For non-parametric surfaces it is trickier
  - directly use 3D coordinates (body or world)
    - must project one out





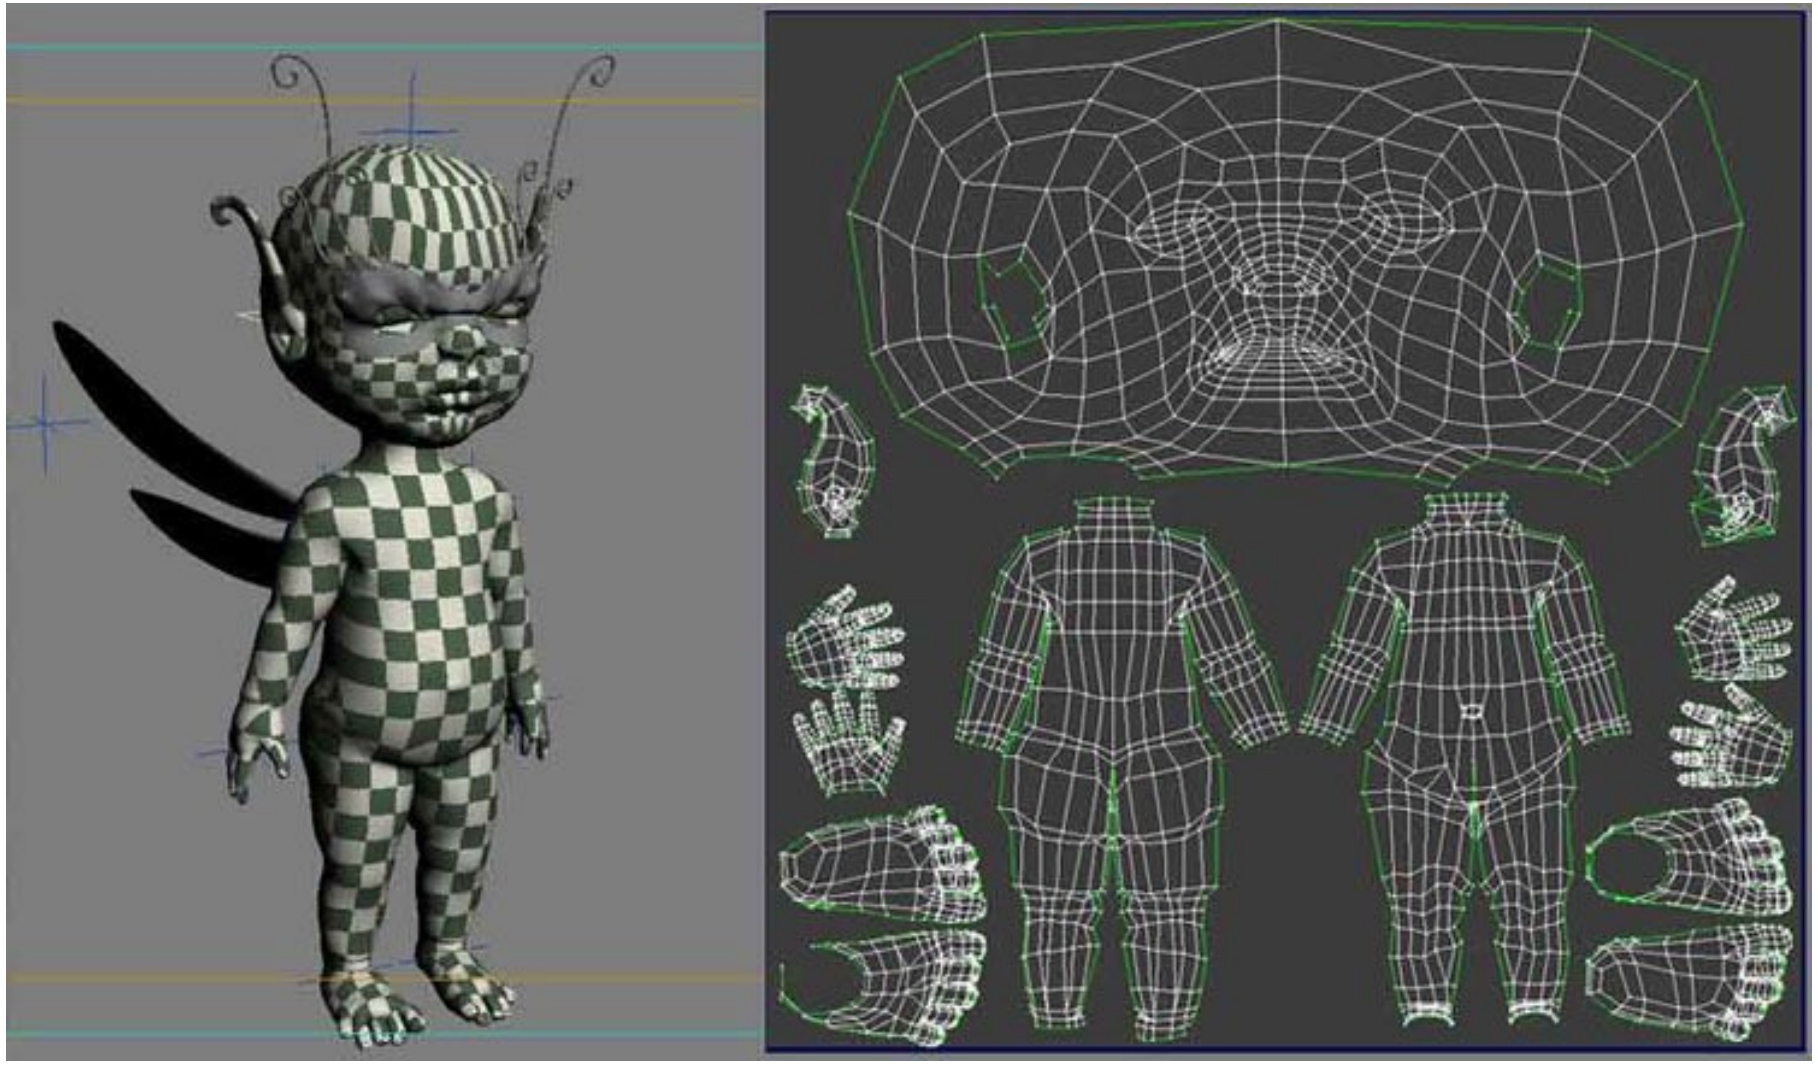
Examples of coordinate functions

- Non-parametric surfaces: project to parametric surface

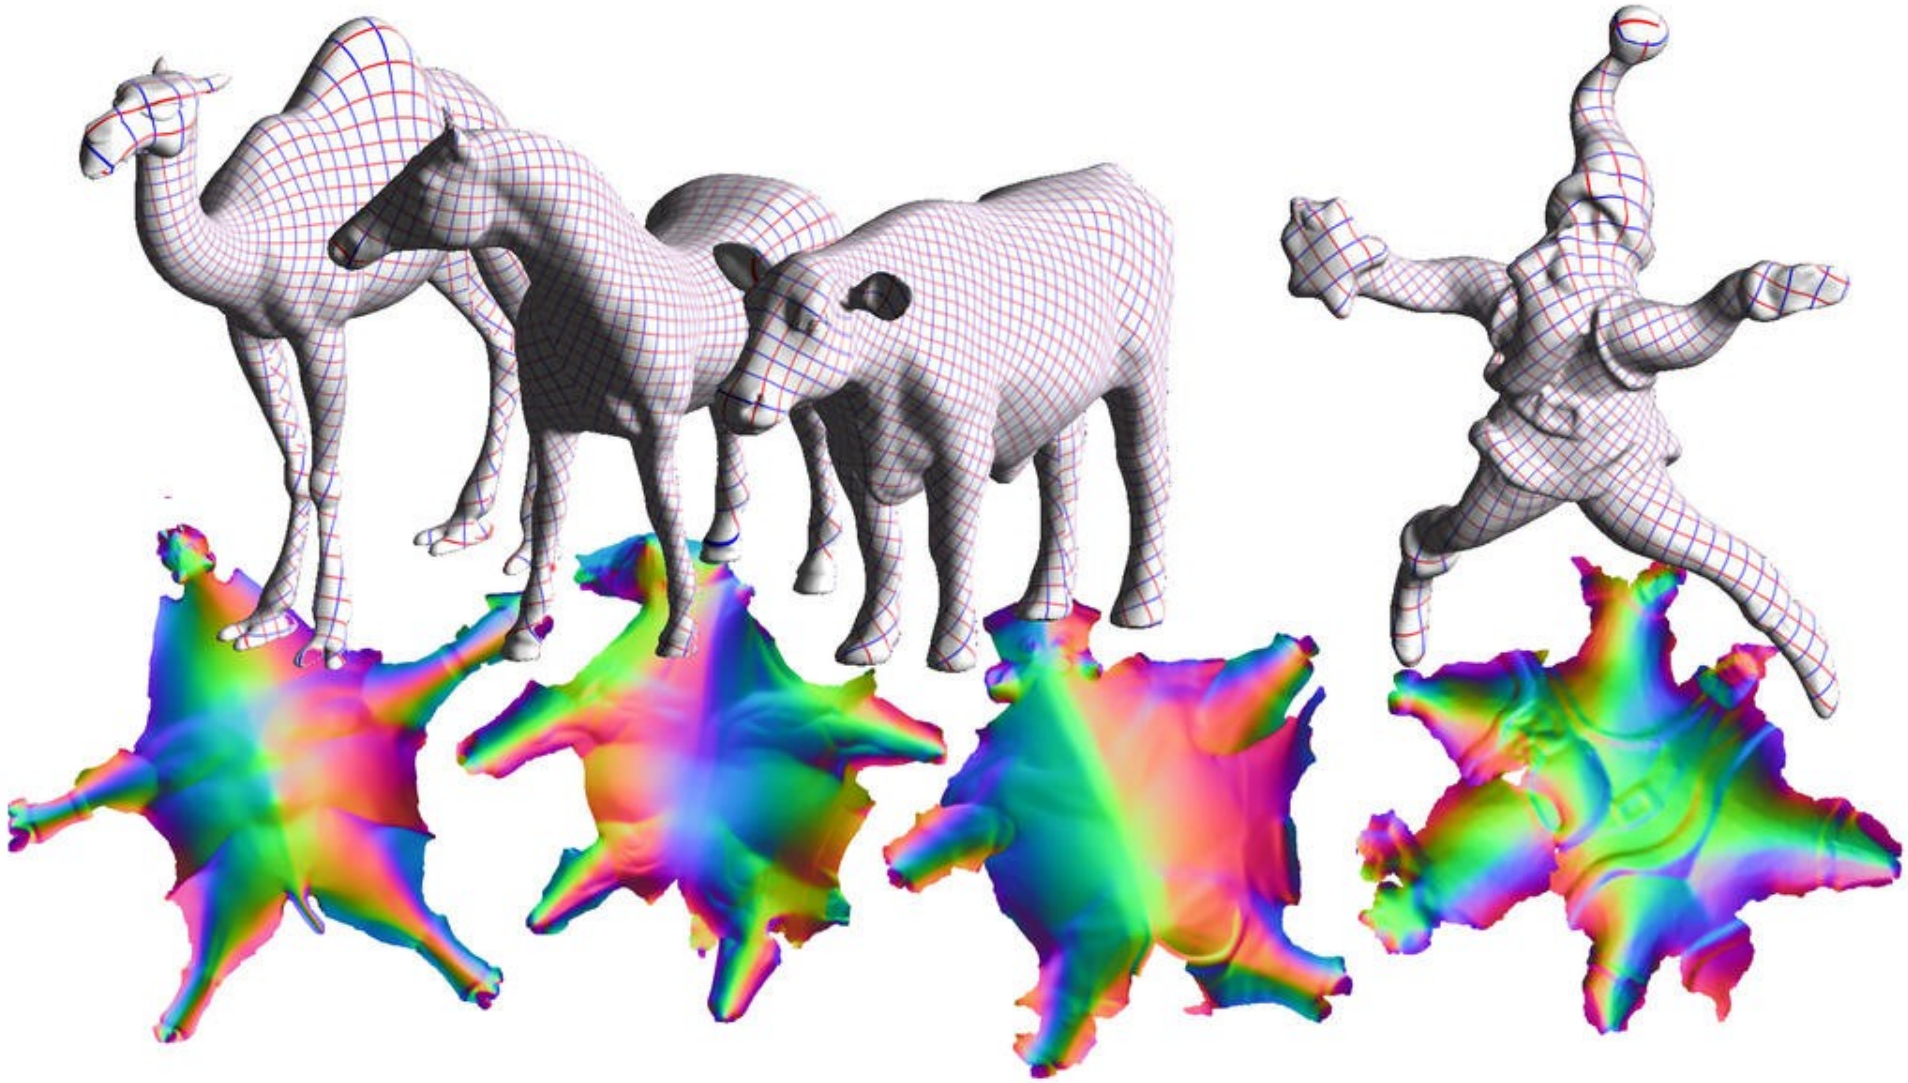


[Moller & Haines 2002]

UV texture map example

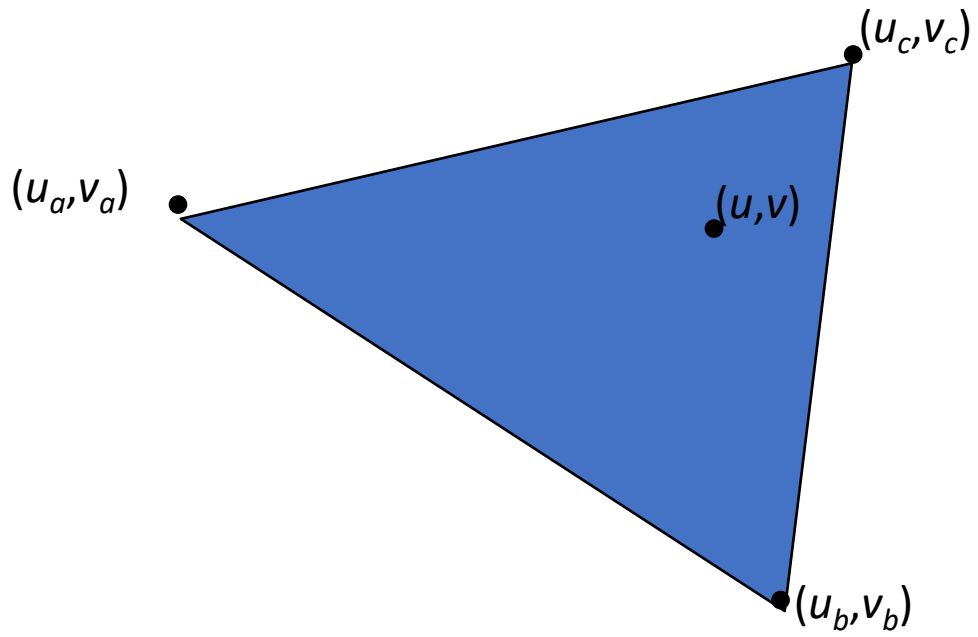


ABF++



Examples of coordinate functions

- Triangles
  - specify (u,v) for each vertex
  - define (u,v) for interior by linear **barycentric** interpolation



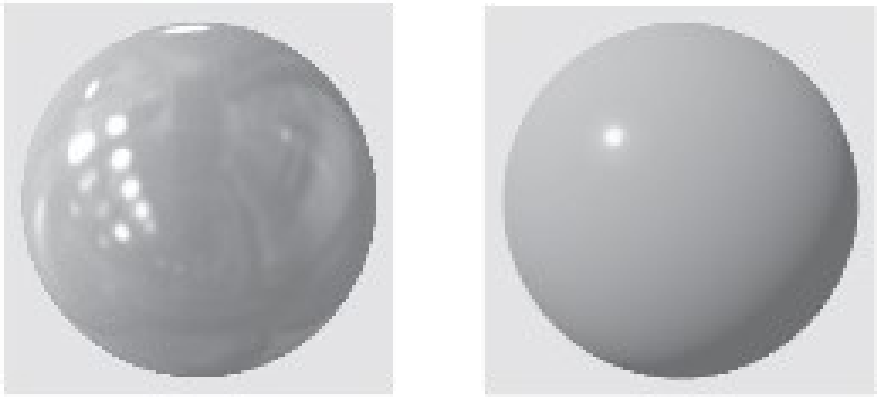
Based on slides by Steve Marschner

Texture coordinates on meshes

- Texture coordinates become per-vertex data like vertex positions
  - can think of them as a second position: each vertex has a position in 3D space and in 2D texure space
- How to come up with vertex (u,v)s?
  - use any or all of the methods just discussed
    - in practice this is how you implement those for curved surfaces approximated with triangles
  - use some kind of optimization (or an artist)
    - try to choose vertex (u,v)s to result in a smooth, low distortion map

Reflection mapping

- Early (earliest?) non-decal use of textures
- Appearance of shiny objects
  - Phong highlights produce blurry highlights for glossy surfaces.
  - A polished (shiny) object reflects a sharp image of its environment.
- The whole key to a shiny-looking material is providing something for it to reflect.

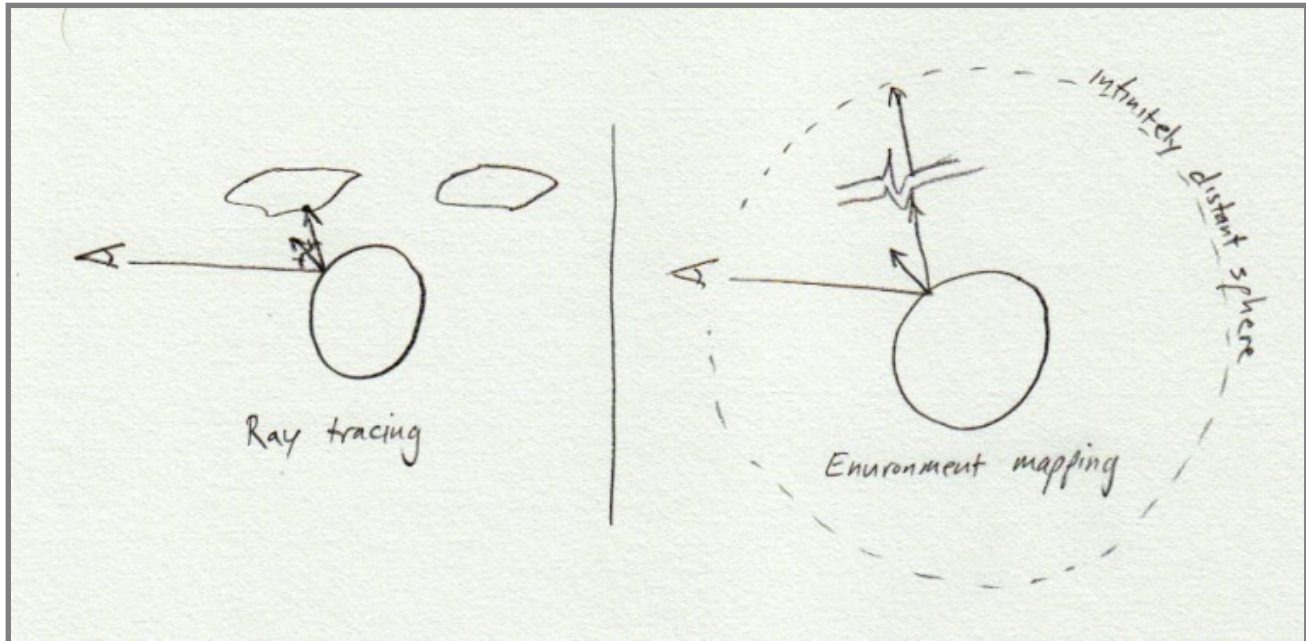


[Dror, Willsky, & Adelson 2004]

(left) A shiny sphere rendered under photographically acquired real-world illumination. (right) The same sphere rendered under illumination by a point light source.

Reflection mapping

- From ray tracing we know what we'd like to compute
  - trace a recursive ray into the scene—too expensive
- If scene is infinitely far away, depends only on direction
  - a two-dimensional function



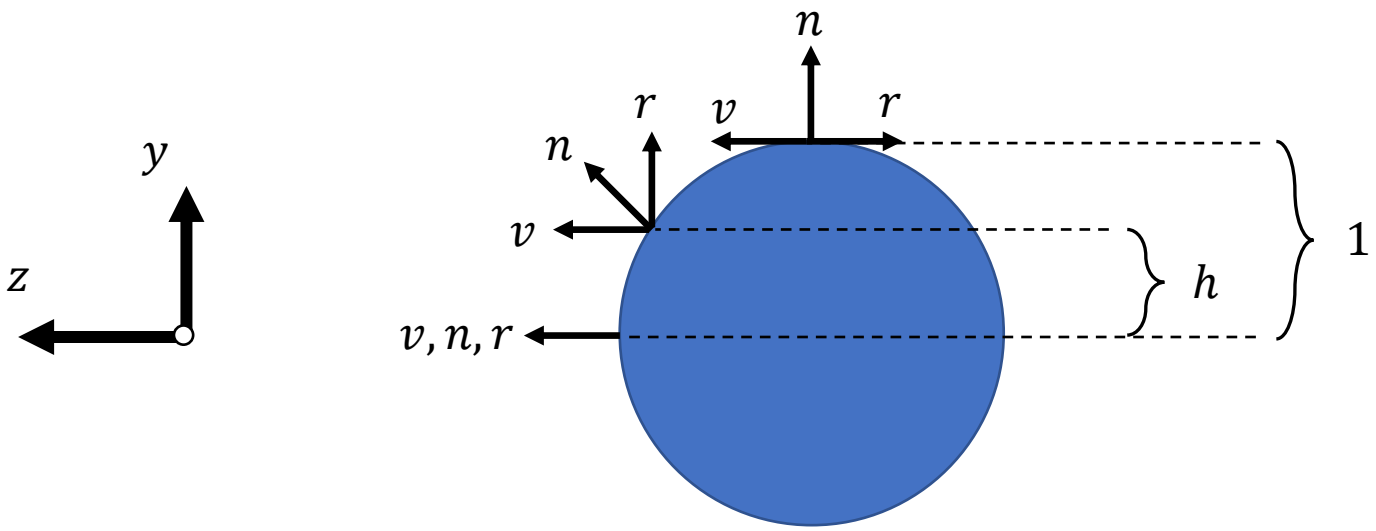
Environment map

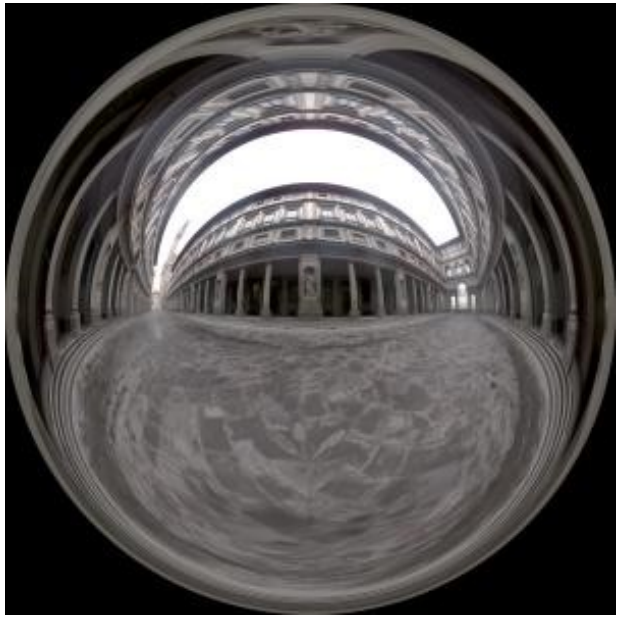
- A function from the sphere to colors, stored as a texture.

[Blinn & Newell 1976]

Spherical environment map

- If assuming distant viewer (orthographic projection) then reflected viewing direction only depends on normal
  - The x and y coordinate of the 3D normal are in $[-1,1]^2$ and can be easily remapped to $[0,1]^2$ with a windowing transform to use as texture coordinates in the sphere map shown at right.





[Paul Debevec]

Based on slides by Steve Marschner

Environment Maps

[Paul Debevec]

[CS467 slides]

Cube environment map

- The common modern approach
- How to do the texture lookup?
- Advantages?
- Disadvantages?

[Ned Greene]

Normal mapping

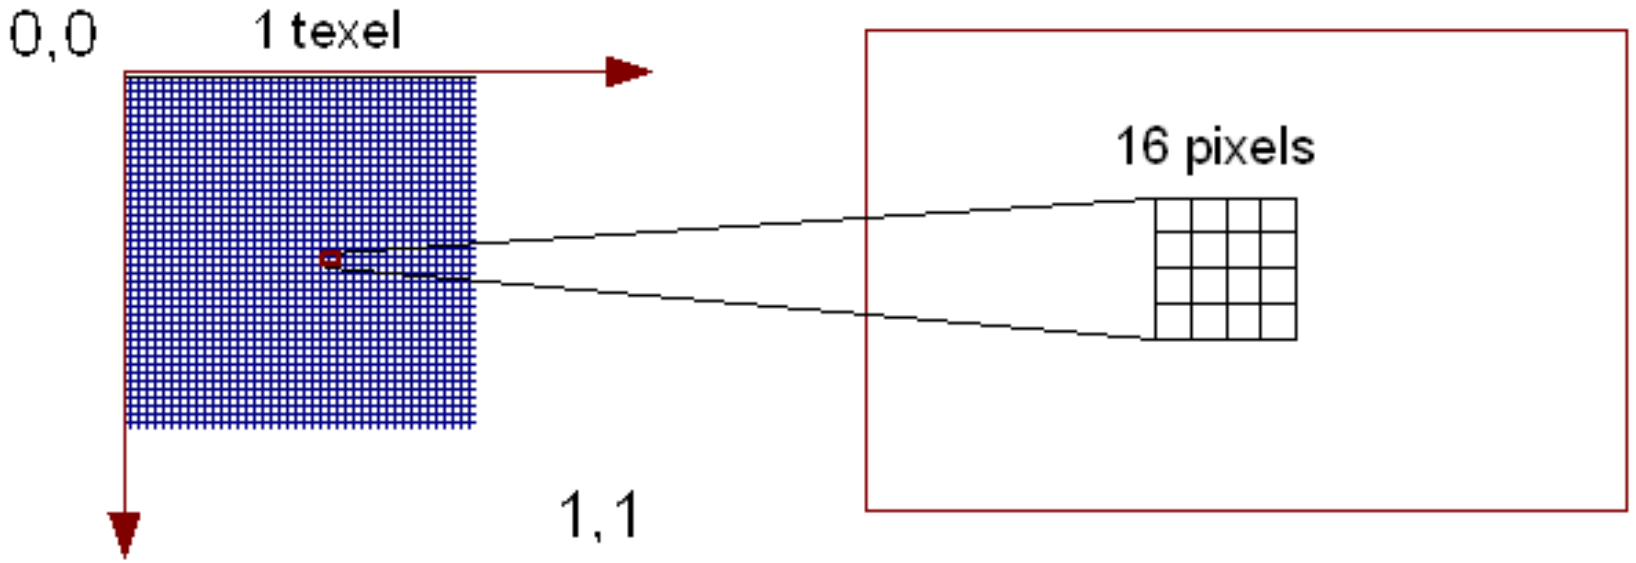
Another definition

Texture mapping: *a general technique for storing and evaluating functions.*

- They’re not just for shading parameters any more!

Texture mapping – sampling problems

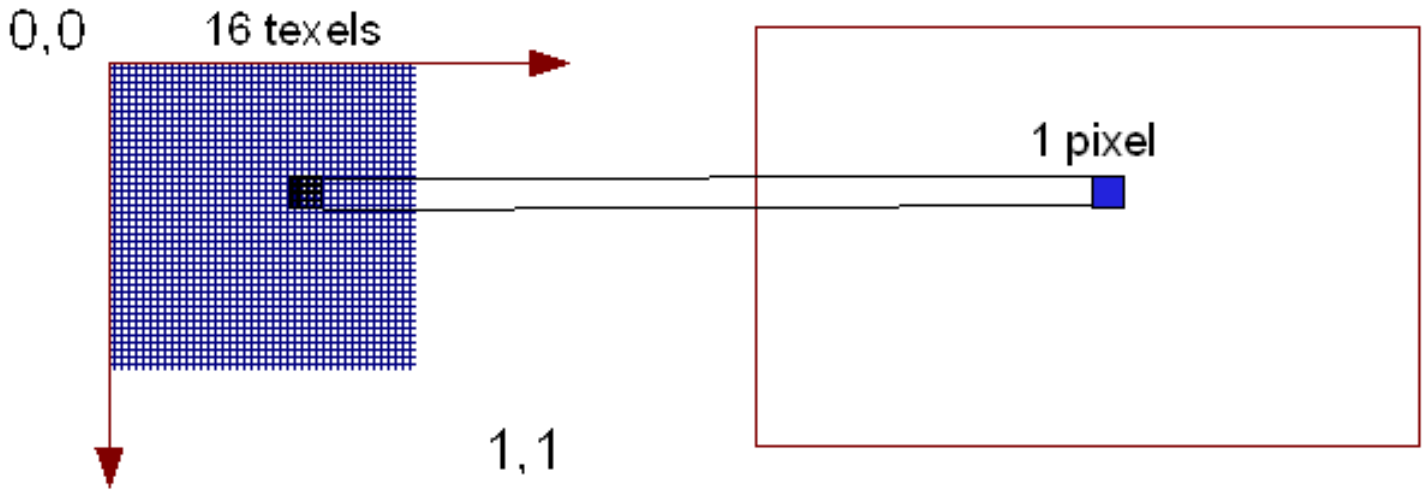
- Too few texels map to a large region of the image
  - **Texture Magnification** when a textured objects are viewed up close
  - Can use nearest texel, or map **bi-linearly** the 4 nearest



https://cs.senecac.on.ca/~chris.szalwinski/archives/gam666.073/content/textu.html

Texture mapping – sampling problems

- Too many texels map to a single image pixel
  - **Texture Minification** when textured objects are small and far (in background)
  - Can use nearest texel, or bi-linearly combine the 4 nearest, but this quickly fails when there is too much minification

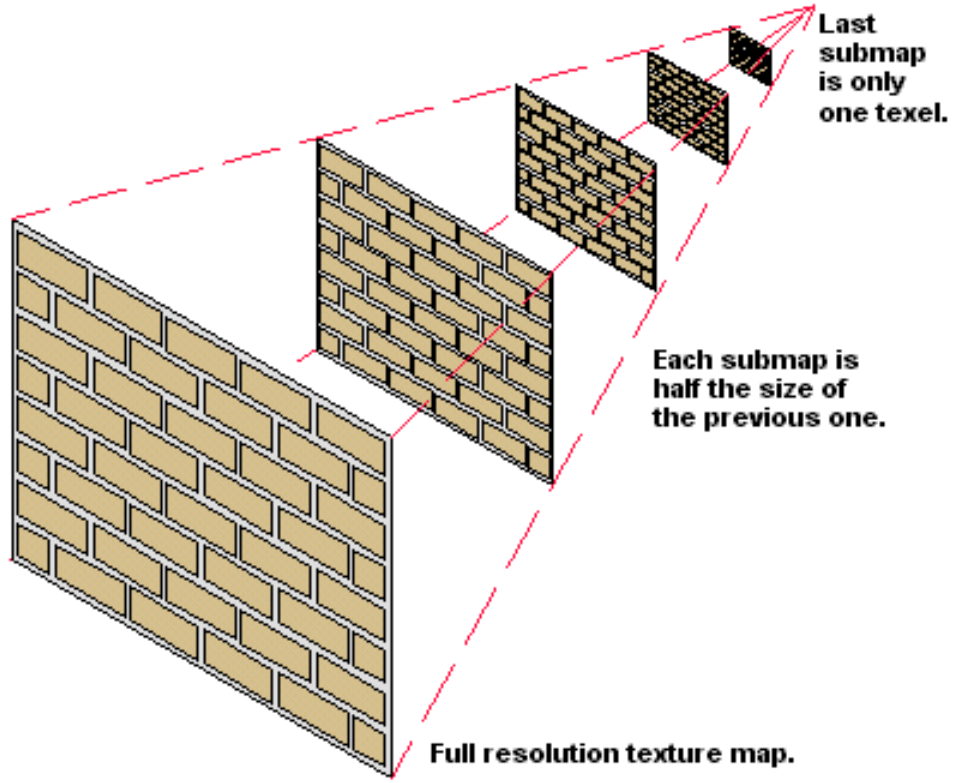


https://cs.senecac.on.ca/~chris.szalwinski/archives/gam666.073/content/textu.html

Texture mapping – sampling problems

- **Mipmapping** constructs texture at many scales, improves minification
  - Choose best level from speed the rasterizer is stepping through texture space
  - Can linearly interpolate between two levels to improve quality

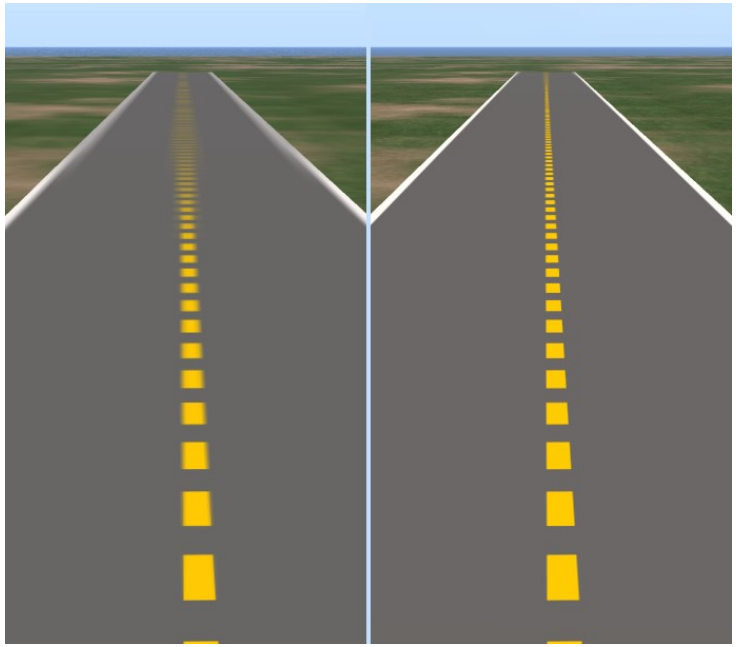
LINEAR_MIPMAP_LINEAR uses 8 samples, bi-linear interpolation of 4 samples at the two closest mipmap resoultions, then blending these two together (that is, trilinear interpolation)

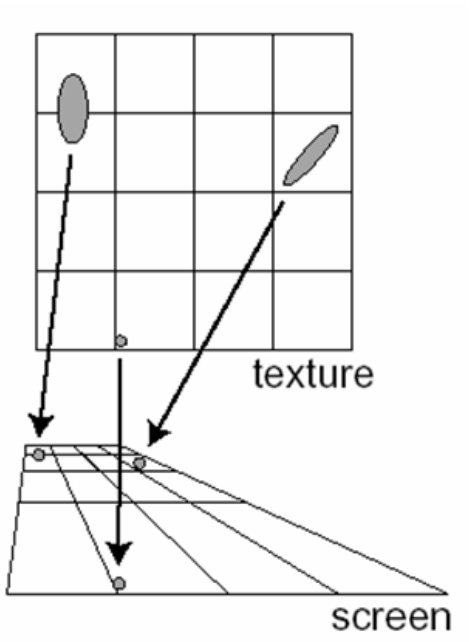


http://www.shinvision.com/wp-content/uploads/2009/06/mipmap.gif

Texture mapping – sampling problems

- ***Anisotropic filtering*** can further improve quality by avoiding the use of low resolution mipmaps.
  - Useful for when texture sampling only requires minification in one direction,
  - Choose samples based on where they are needed!

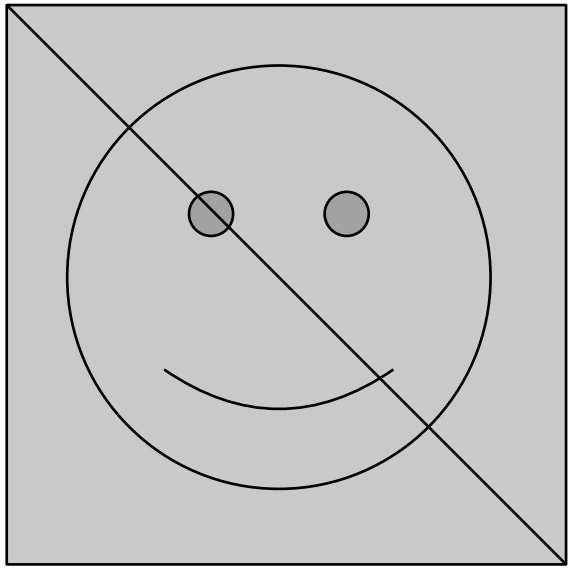




Based on slides by Steve Marschner

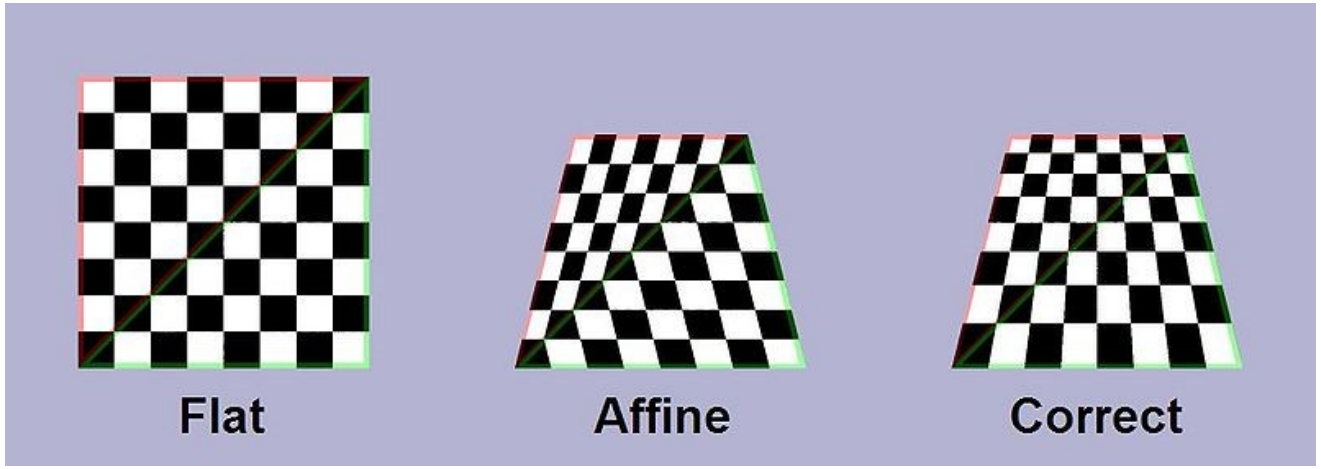
Texture mapping issues

- Quadrilaterals



Texture mapping issues

- Perspective projection



[wikipedia]

Affine texture mapping directly interpolates a texture coordinate u_α between two endpoints u_0 and u_1:

$$u_\alpha = (1-\alpha)u_0 + \alpha u_1 \text{ where } 0 \leq \alpha \leq 1$$

Perspective correct mapping interpolates after dividing by depth z, then uses its interpolated reciprocal to recover the correct coordinate:

$$u_\alpha = \frac{(1-\alpha)\frac{u_0}{z_0} + \alpha\frac{u_1}{z_1}}{(1-\alpha)\frac{1}{z_0} + \alpha\frac{1}{z_1}}$$
